Abstract: To find out a good candidate of cosmetic source and screened for antimicrobial, antioxidative and
whitening activities. In the antioxidiant experiment, supercritical Halopteris scoparia extraction (SHE) and
hydrothermal Halopteris scoparia extraction (HHE) were slightly different depending on the experimental
method (Total polyphenol content measurement, DPPH radical scavenging ability, ABTS radical scavenging
ability, and SOD-like activity) and in the enzyme experiment (Elastase, Tyrosinase inhibition activity), the
supercritical extract was more effective. In supercritical fluid, Halopteris scoparia extracts showed good
antimicrobial activity against Propionibacterium acnes, Staphylococcus aureus, Bacillus subtilis and Escherichia
coli but hydrothermal extract had no effect about the rest of the strains. Therefore, it can be expected that the
supercritical Halopteris scoparia extract with excellent antibacterial activity can be used as a cosmetic material.

Keywords: Halopteris scoparia, Seaweed, Supercritical fluid, Antimicrobial, Cosmetics

Introduction

Recognition of cosmetics is gradually deviating from the category of “products used to clean or beautify the
human body and preserve skin or hair in good health”, and attention is focused on how to grow younger and
healthily with age. Accordingly, the emergence of functional cosmetics has emerged, and materials that are safe
for the human body have been gradually developed, enabling the development of sanitary aid and functional cosmetics.

Hydrothermal extraction and solvent extraction are mainly utilized to obtain high purity functional extracts
required in the cosmetics and food industry, and solvent extraction methods are used often to obtain various active
ingredients. However, there are problems with solvents such as a skin irritation and environmental pollution caused
by large amounts of waste solvents. Interest in supercritical fluid extraction process using supercritical carbon
dioxide is increasing as an environment-friendly alternative technology for compensate and improve the
shortcomings of existing natural effective extraction process. Extracting supercritical fluids uses carbon dioxide that
is harmless to the human body. Supercritical fluid is defined as “A fluid that is heated to a temperature higher than
critical temperature and greatly increased in density as pressure increases above critical pressure,” which has a
unique characteristic that differs from conventional solvents by having the properties of both liquids and gas
at the same time and is a heavy fluid that fills a confined space like a machine [1]. For supercritical carbon dioxide, it is
possible to extract the active ingredient for almost any range of molecular weight. Currently, studies are actively
conducted on various natural extracts using supercritical carbon dioxide.

Marine organisms that live in the oceans have been found to contain several compounds that distinguish them
from terrestrial organisms, marine life by showing the recent sponges, polychaeta and the extract of seaweed
bioactive has attracted attention as a raw material for the development of cosmetic. Representative compounds
exhibit physiological activity in the current marine organisms to extract is known as tannins, terpenes, phenol,
halogen, and catechin [2]. Seaweed extracts contain natural compounds involved in antioxidants, antibacterial, anti-
cancer, anti-inflammatory, anti-blood coagulation and immune - control actions, so they are a leading class of new
drug development that can be used for disease prevention and treatment [3-5]. In this context, Halopteris scoparia,
species of phaeophycean, is already known to limit the expansion of adipose tissues by inhibiting pre-adipocyte
differentiation.

Therefore, this study intends to evaluate the antibacterial and antioxidant properties of Halopteris scoparia as a
 Cosmetic material and to provide basic data for the development of cosmetic materials based on this.

Materials and Experiments

2.1 Instruments and reagents

The equipment and reagents used for each experiment are as follows. The solutions used for the polyphenol,
DPPH test used in the antioxidiant and antibacterial tests were obtained from Sigma Aldrich (USA). R6 (hexa-D-
arginine) was obtained from Dermafirm Co. (Seongnam, Korea). The equipment used in the experiment is as
follows. Supercritical fluid extraction (ARI instrument, Namyangju, Korea), Absorption spectrophotometer
(SYNERGY HTX multi-mode reader, Bio Tek, Seoul, Korea), Centrifugal separator (Supra-25K, Hanil
Scientific Inc., Gimpo, Korea). Thermostat (Changshin Science, Seoul, Korea), High pressure processor
(Microfluidizer, Picomax, Seoul, Korea), Particle size analyzer (Nanoctrac Flex, DREAM Co., Suwon, Korea),

Antimicrobial, Antioxidative, Elastase and Tyrosinase Inhibitory Effect of Supercritical and Hydrothermal Halopteris scoparia Extract

2.2 Sample extraction

In the hydrothermal extraction method, purified water was added to the Halopteris scoparia powder and extracted for 4 hours in a thermostat at 80°C and filtered and freeze dried. In the supercritical extraction method, the pressure of the extractor was set to 350 bar and the temperature to 60°C. The pressure of the separator was set to 40 bar, the temperature was set to 25°C, and the flow rate of CO2 was extracted at 60 mL/min for 150 minutes.

2.3 Total polyphenol content measurement

Quantification of polyphenol was measured by Folin-denis [6]. To 100 µL of the Folin-Ciocalteu reagent, add 100 µL of the diluted sample solution and reacted at room temperature for 3 minutes. 100 µL of Na2CO3 solution was added and the absorbance was measured at 760 nm with an ELISA reader. The average value of polyphenol contents by concentration was calculated. The calibration curves were quantitatively analyzed using garlic acid as a standard.

2.4 Antioxidant activity measurement

1) DPPH radical scavenging ability

The effect about DPPH radical scavenging was measured by Blois method [7]. To 100 µL of the extract solution, 120 µL of 0.45 mM 2,2-diphenyl-1-picrylhydrazyl solution was added and reacted in the dark room for 30 minutes. Absorbance was measured at 530 nm with an ELISA reader.

\[
\text{DPPH radical scavenging activity (\%)} = \left( \frac{\text{Absorbance of DPPH solution} - \text{absorbance of samples}}{\text{absorbance of DPPH solution}} \right) \times 100
\]

2) ABTS radical scavenging ability

The effect about ABTS radical scavenging was measured by Re method [8, 18]. The ABTS radical cation (ABTS+) was produced by reacting 7.2 mM stock solution ABTS with 2.64 mM potassium persulphate (final concentration) and allowed the mixture to stand in the dark for at least 24 hours at room temperature before use. The ABTS+ solution was diluted to an absorbance 0.7 ± 0.05 at 745nm. Absorbance was measured 20 minutes after the initial mixing of different concentrations of the extracts. The ABTS+ decolorisation capacity of the extracts were compared with the standard ascorbic acid.

\[
\text{ABTS radical scavenging activity (\%)} = \left( \frac{\text{Absorbance of ABTS solution} - \text{absorbance of samples}}{\text{absorbance of ABTS solution}} \right) \times 100
\]

2.5 Measurement of Superoxide Dismutase (SOD)

SOD-like activity was performed by modifying Marklund's method [9]. The experiment was carried out using SOD Assay Kit (BCBV5418). 20 µL of buffer solution and 20 µL of enzyme working solution were added to 20 µL of each sample solution, and incubation was carried out at 37°C for 20 minutes. The absorbance at 420 nm was measured by an ELISA reader.

\[
\text{SOD similar activity (\%)} = \left[ 1 - \left( \frac{\text{Absorbance in the sample addition group}}{\text{absorbance in the no additives}} \right) \right] \times 100
\]

2.6 Measurement of elastase

Elastase inhibitory activity was measured by Cannell [10]. The experiment was carried out using EnzCheck® elastase Assay Kit (E-12056). 1x Reaction buffer was used to dilute the Halopteris scoparia extract sample and incubated in a 96-well black plate using 100 mg/L DQ elastin solution and 0.2 U/mL elastase for 30 minutes at room temperature. Absorbance was measured at 485 nm excitation and 528 nm emission fluorescence with an ELISA reader.

\[
\text{Inhibition rate of elastase (\%)} = \left[ 1 - \left( \frac{\text{Absorbance in the sample addition group}}{\text{absorbance in the no additives}} \right) \right] \times 100
\]

2.7 Measurement of tyrosinase activity

Tyrosinase activity was modified by the method of Kubo [11]. 0.1 M sodium phosphate buffer (pH 6.5) and 50 µL with purified water to 40 µL, 2000U mushroom tyrosinase (Sigma, T3824) 5 µL pre-manufacturing a total of 95 µL to minutes after the extract 5 µL was placed. 0.03% L-tyrosine 50 µL was added and incubated at 37°C for 10 minutes. Kojic acid was used as positive control. Absorbance was measured at 475 nm with an ELISA reader.

\[
\text{Inhibition rate of tyrosinase (\%)} = \left[ 100 - \left( \frac{b - b'}{a - a'} \right) \right] \times 100
\]
2.8 Antimicrobial experiment

The disc diffusion test was performed to determine the antimicrobial activity of Halopteris scoparia [12]. Staphylococcus aureus (S. aureus), Escherichia coli (E. coli), Bacillus subtilis, and Propionibacterium acnes (P. acnes) were purchased from KCM and KCTC. The strains Staphylococcus aureus, Escherichia coli and Bacillus subtilis were cultured in Muller-Hinton medium at 37°C for 24 hours, re-cultured once, and then absorbed at 600 nm using a spectrophotometer. Propionibacterium acnes was incubated in a sealed container for 72 hours, re-incubated once, and then absorbed at 600 nm using a spectrophotometer. The culture conditions are shown in Table (1).

2.9 Statistical processing

All experiments were repeated 3 times. All values were expressed as mean and standard deviation and the difference between the values was analyzed by t-test, one-way analysis of variance (ANOVA) with Post hoc(LDS) respectively.

Results

3.1 Yield

Halopteris scoparia was extracted with hydrothermal and supercritical. Each yield was 12.92 % in HHE (Hydrothermal Halopteris scoparia extraction) and 0.1 % in SHE (Supercritical fluid Halopteris scoparia extraction).

3.2 Total polyphenol content

To measure the total polyphenol content, the results of the comparison of the extraction process of Halopteris scoparia extract are shown in Table 2.

3.3 Antioxidant efficacy of Halopteris scoparia

1) DPPH radical scavenging ability

DPPH radical is a method of measuring the activity of a hydrogen donor. When they get electron from phenolic compounds or aromatic amines, the color is turned purple to yellow by proton-radical scavengers [13]. The antioxidant activity of the extracts was shown between 0.63 ~ 5 mg/ml. In 5 mg/ml, the radical scavenging activity was 67 % in hydrothermal extraction and 94% in supercritical extraction Figure (1).

2) ABTS radical scavenging ability

ABTS radical cation is a deep blue-green radical that reacts with antioxidants and is characterized by discoloration by light green. The antioxidant effect of ABTS free radicals produced by the reaction of potassium persulfate is measured by the degree of discoloration of the radical-specific cyan color to light green [14]. The antioxidant activity of the extracts was shown between 0.63 ~ 5 mg/ml. The concentration - dependent results were showed and IC50 of HHE is 61.39 ppm and IC50 of SHE is 384.58 ppm Figure (2).

3.4 Superoxide Dismutase (SOD) measurement

SOD-like activity assay is an antioxidant activity assay using color development by automatic oxidation [15]. The substances that inhibit superoxide in the samples used in the experiment can inhibit the oxidation by oxidation in the presence of SOD or SOD-like active substances. In the SOD (Superoxide dismutase) - like experiments, IC50 of HAE is 364.57 ppm Figure (3).

3.5 Measurement of elastase

The elastase which is presented in the dermis of the skin is an enzyme capable of degrading various proteins including fibronectin, collagen and elastin which maintains elasticity of the skin in the dermis [16]. The elastase inhibitory effect which is effective for improving the wrinkles of the skin was measured according to the concentration dependent and IC50 of HHE is 1419 ppm and IC50 of SHE is 1875 ppm in Figure (4).
3.6 Measurement of tyrosinase activity

Melanin is a pigment produced by melanomas, one of the cell organelles. Melanin is produced by the action of various enzymes such as tyrosinase, tyrosinase-related protein 1 (TRP1) and tyrosinase-related protein 2 (TRP2) in melanomas [17]. Among them, tyrosinase is a major regulatory enzyme that plays a role in the oxidation of tyrosine to DOPA quinone after being hydrolyzed with DOPA and is related to melanin. The lowest tyrosinase activity of 47% was observed at the concentration at 667 mg/ml of SHE in Figure (5).

3.7 Antimicrobial experiment

The antimicrobial test was conducted three times using the paper disc method. The results of the clear zone measurement are shown in Table (3). As a result of the antimicrobial test, the supercritical fluid *Halopteris scoparia* extraction had antimicrobial effect in the four strains. In the case of *Propionibacterium acnes* strain, the largest clear zone of 23.00±1.00 mm was found at the concentration of 20 mg/ml. In the other hand, in experiments with the same conditions, hydrothermal *Halopteris scoparia* extraction had no effect in all strains. Melanin is a pigment produced

*Growth inhibition line, H: Hydrothermal Halopteris scoparia extraction. S: Supercritical fluid Halopteris scoparia.

Clear zone for methyl paraben (positive control) is 13.10±0.10mm at 20mg/ml only in P. acnes strain.

Conclusions
This study was conducted to evaluate physiological activity of Halopteris scoparia extract. After extraction with Halopteris scoparia using hydrothermal and supercritical carbon dioxide, various physiological activities were examined. The total concentration of polyphenol compounds was determined to be 20.43 mg/g of hydrothermal Halopteris scoparia extract (HHE) and 9.99 mg/g of supercritical Halopteris scoparia extract (SHE). In DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging assay, ascorbic acid was used as positive antioxidant control. The percentage of inhibition and IC50 were measured. The IC50 of HHE is 2823 ppm and the IC50 of SHE is 1833 ppm. In ABTS (2,2-azino-bis(3-ethylbenzothiazoline - 6-sulfonic acid) diammonium salt) radical scavenging assay, ascorbic acid was used as positive antioxidant control. The percentage of inhibition and IC50 were measured. The IC50 of HHE is 61ppm and the IC50 of SHE is 385 ppm. The elastase inhibitory assay showed concentration dependence and the IC50 of HHE is 1419 ppm and the IC50 of SHE is 1875 ppm. In mushroom tyrosinase inhibition experiments, tyrosinase inhibition of SHE was 47% at 667 mg/mL. In the antimicrobial experiments, maximum clear zones of SSE represented 17.00 mm in Propionibacterium acnes, 12.90 mm in Bacillus subtilis, 11.00 mm in Escherichia coli, 9.20 mm in Staphylococcus aureus. And maximum clear zones of SHE represented 12.30 mm in Propionibacterium acnes, but hydrothermal extract had no effect about the rest of the strains.

Therefore, it can be expected that the supercritical fluid Halopteris scoparia extract with excellent antibacterial activity can be used as a cosmetic material.
